## Def(Secant Line):

A secant line of a function is a line which goes through at least two points of the function.

**Example(Secant Line):**

Let's say we have a function,  $f(x) = 2x^2$ . One of its secant lines would be the line going through the points:

$$(1, f(1)) = (1, 2) \text{ and } (2, f(2)) = (2, 8)$$

Since we know the points this particular line goes through, we can use the point-slope formula(  $y - y_0 = m(x - x_0)$  ) to find its equation.

**Example(Secant Line):**

First we need to find its slope,  $m$ .

Since our line goes through the points

$$(1, f(1)) = (1, 2) \text{ and } (2, f(2)) = (2, 8)$$

we know the slope is:

$$m = \frac{\Delta y}{\Delta x} = \frac{f(2) - f(1)}{2 - 1} = \frac{8 - 2}{2 - 1} = \frac{6}{1} = 6.$$

**Example(Secant Line):**

Now that we know the slope we need to chose one of the two points and plug everything into the point-slope formula.

Let's use the point (2, 8). Then plugging everything in we get,

$$y - 8 = 6(x - 2)$$

Solving for  $y$  we get the equation of our line,

$$y = 6x - 4$$

## Example(Secannt Line):

Question:

Let's say we have a function,  $f(x)$  and a secant line that goes through two points. What happens if we fix one of those points, say  $x = a$  and move the other one,  $a \pm h$ , to it?

So our secant line would be the line through:

$$(a, f(a)) \text{ and } (a \pm h, f(a \pm h))$$

Answer:

Our secant line would "approach" the tangent line of  $f(x)$  at  $x = a$

## Def(Tangent Line):

A tangent line of a function is a line which "touches" at least one point of the function, and has the same slope as the function at that point.

**Example(Tangent Line):**

Let's use the same function as before,  $f(x) = 2x^2$ . And let's consider the line that "lays tangent to  $f(x)$  at  $x = 1$ ."

$$(1, f(1)) = (1, 2)$$

Since we know the point this particular line goes through, we can use the point-slope formula(  $y - y_0 = m(x - x_0)$  ) to find the equation that describes it.

## Example(Tangent Line):

First we need to find its slope,  $m$ .

Since our line goes through the point

$$(1, f(1)) = (1, 2)$$

and has the same slope as our function  $f(x)$  at  $x = 1$ , we know the slope is:

$$m = \lim_{h \rightarrow 0} \frac{f(1+h) - f(1)}{(1+h) - (1)} = \lim_{h \rightarrow 0} \frac{(2(1+h)^2) - (2(1)^2)}{h}$$

$$= \lim_{h \rightarrow 0} \frac{(2h^2 + 4h + 2) - (2)}{h} = \lim_{h \rightarrow 0} \frac{(2h^2 + 4h)}{h} = \lim_{h \rightarrow 0} (2h + 4) = 4$$

### Example(Tangent Line):

Now that we know the slope we need to plug everything into the point-slope formula, to get.

$$y - 2 = 4(x - 1)$$

Solving for  $y$  we get the equation of our line,

$$y = 4x - 2$$

## Example(Tangent Line):

The slope of the tangent line of our function at  $x = a$  is also the slope of our function at  $x = a$ .

We call the slope of our function at  $x = a$ , the *derivative* of our function at  $x = a$

## The Limit Definition of the Derivative of $f(x)$ at a point $x = a$ :

Given a function  $f(x)$ , its derivative at  $x = a$  is,

$$\lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = f'(a)$$

We can generalize this to all points in our domain by "exchanging"  $a$  with  $x$ . And in doing so, we will have derived the function describing the derivative of our function.

## The Limit Definition of the Derivative of $f(x)$ :

Given a function  $f(x)$ , its derivative is,

$$\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = f'(x)$$

**Def(Differentiable at a Point  $x = a$ ):**

## Def(Differentiable on an Interval):

## The Derivative Rules:
